

What's the point of doing this? This is an example of how Unfair Content Detection works. It analyzes your content, identifies any strings that are uncommon for this type of text, and then asks you to provide a response that has a high probability of being safe. It's not perfect, but it can still save you from having your site flagged as spammy or malicious. Once you submit your answer, the script will analyze the response and tell you if it's correct or incorrect. After 1-2 minutes wait time, it should tell if it is unsafe or not safe based on statistics about these strings. If you see "too many unrecognizable words in the answer" message when the "Too Many Unrecognizable Words in The Answer" box is checked, then your answer contains too many different unknown words. These are common mistakes that are often made by people who are just starting to learn how to construct an English sentence. By adjusting your string length or adding more known words to increase the accuracy of this detection, this test can be significantly improved. This test will check for any invalid javascript in your page. It can also detect code injection attacks through frames or iframes. The following tests check whether your site is over-optimized for search engines. It tests the number of links to other sites on your site, and it checks for any link-rot on those sites. There is a difference between SEO and website optimization. Optimizing a website for search engines will increase the amount of visitors to your site from search engines, but it will not increase your conversion rate or improve your site's usability or ranking in the search engines. In order to optimize a website for search engine use, you have to optimize it for your users – all of them – including those who browse without using a search engine. This test checks only whether the page contains excessive links pointing to other webpages, which can slow down or even completely prevent a page from loading. This test checks whether you have implemented the pagination and canonical tags on your site. The Sitemap Generator can automatically generate a sitemap for you. The ping service can notify major search engines and directories of the existence of a site's XML sitemap. These files, if submitted correctly, should increase your page's indexing speed by search engines such as Google. By using the sitemap generator, you can ensure that your XML file is properly formatted and that all necessary pages are included in it. This test checks whether your site has broken links. Links that are not working properly are often the cause of high bounce rates. Improperly coded links can also be a sign that you have been hacked or that your site is infected with malware. This test checks whether you have used the robots meta tag on all of your pages, and if so, it reports back to you which pages are restricted for search engine crawlers. Google's Webmaster Guidelines state that you should "not block or redirect PageRank". This means do not use noindex tags, canonical tags, or 301/302 redirects in order to prevent search engines from crawling content on your page.
